Wehkamp Case

Was the Wannagive Campaign Successful?

The campaign performed well at rewarding loyal customers and generated short-term revenue uplift (€310K) but failed to drive lasting engagement and behavioural change.

CAMPAIGN PERFORMANCE

16,030 — Participants
total unique users

~21.8% — Card open rate
average across campaign

1 day — Median streak
above half of users never returned

-70% — Participation drop
after Day 1 — steep cliff effect

KEY BEHAVIOURAL INSIGHTS

5.4% — Long streaks (≥7 days)
of participants only

22% — 2+ day streaks
very low repeat engagement

35.9% — Streak rebuild attempts
tried but rigid mechanics limited retention

High-value — Profile
loyal customers — not new acquisition

BUSINESS IMPACT

€310K — Revenue
incremental during campaign

+38% — Orders
& +30% demand during campaign

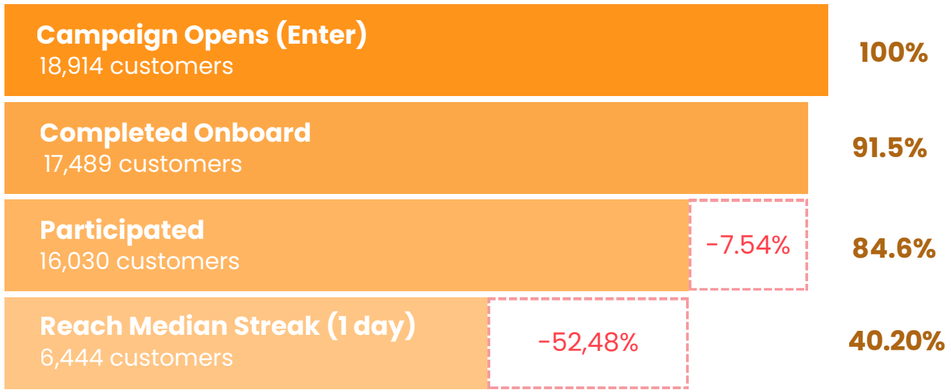
↓ Baseline — Post-campaign
demand returned after campaign ended

2–3× — Lift vs. non-participants
higher lift for participants

High Initial Activation but Sharp Engagement Drop Post First Interaction

16,030	40.2%	21.8%	83,757
Unique participants (Opened ≥1 card)	Enter → Reach Median Streak	Avg Daily Open Rate	Total Cards Opened

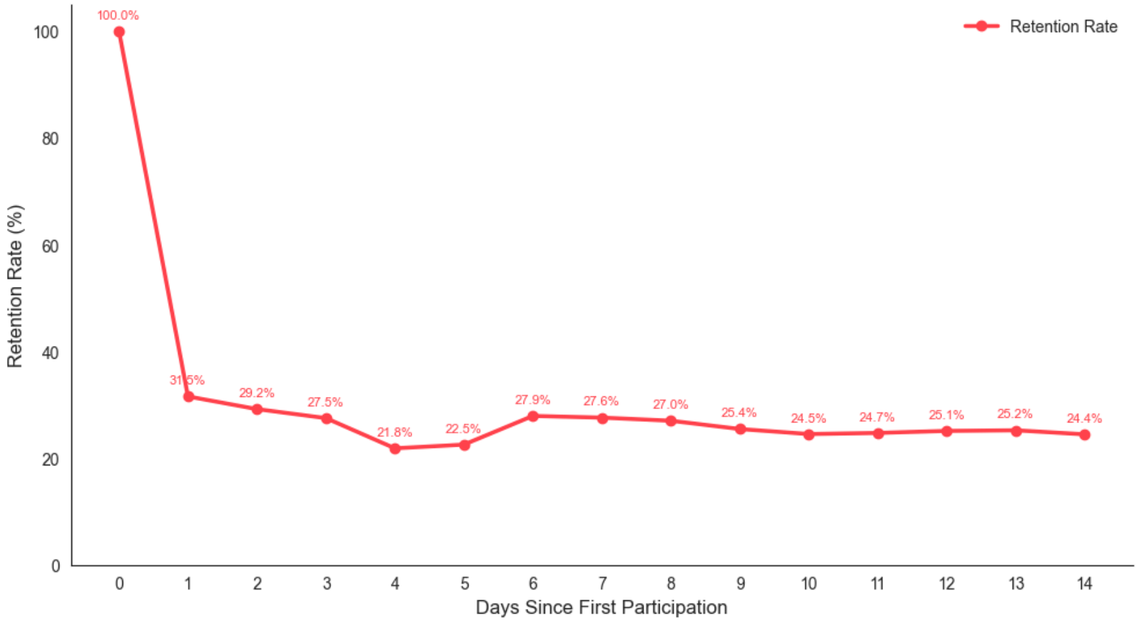
CUSTOMER JOURNEY (%)



- **Onboarding Phase:** For every 10 people who open the app, more than 9 complete the tutorial → UX/UI is not frustrating.
- **Participated Phase:** After understanding how to play, most customers are ready to open a card on the first day.
- **Retention Phase:** A 52,48% drop in participation indicates the campaign struggled to convert trial users into loyal ones. With a median streak of just 1 day over a 22 day campaign, this suggests clear campaign fatigue, as daily app engagement likely felt too demanding relative to the rewards.

⚠️Technical Interface is not the problem, it lies entirely in user motivation

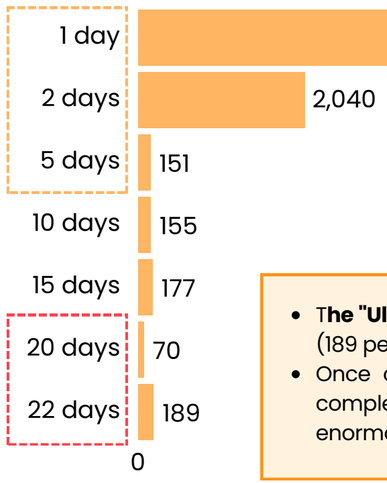
OVERALL RETENTION CURVE



- Nearly 70% of users did not return after the first day → the campaign attracted participants but failed to create a habit from the start.
- **Stabilize from Day 1 to Day 14:** The decrease is very slow and steady. Users who made it through Day 1 tend to stick with the campaign and do not drop off abruptly.

Low Engagement Consistency Over Time

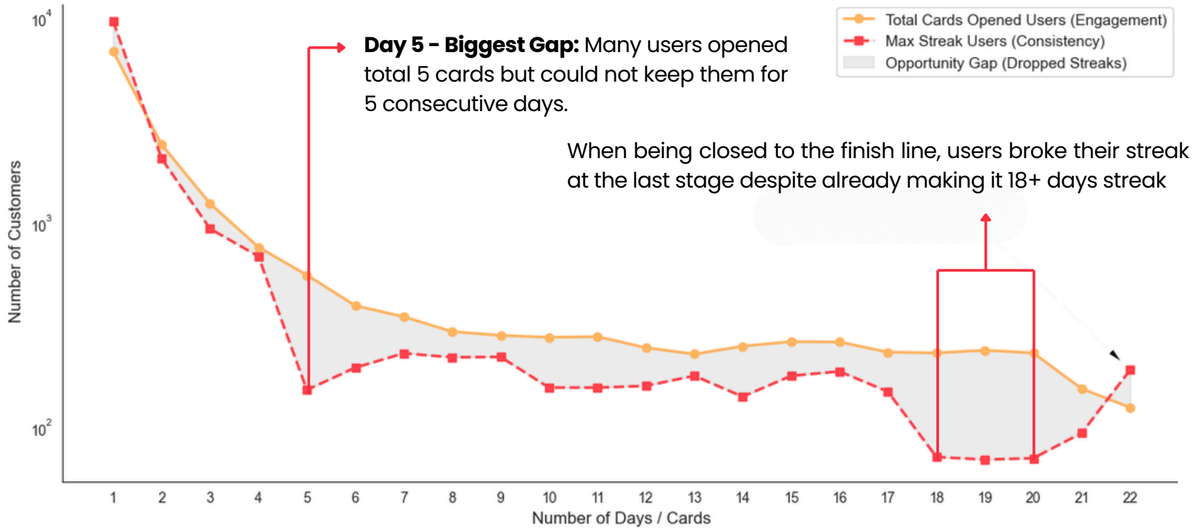
STREAK DISTRIBUTION (NUMBER OF PEOPLE)



Most customers found maintaining a streak of 5 consecutive days difficult, or the €5 reward at this point was not attractive enough to entice them to return on the 2nd or 3rd day (-98,42% from 1st day - 5th day)

- **The "Ultimate Streak" Paradox:** The number of people who reached 22 days (189 people) was higher than the number who stopped at 20 or 21 days.
- Once customers had surpassed the 15-20 day mark, the motivation to complete the final two days to claim the highest reward (€25) was enormous → **This group had formed a "daily routine".**

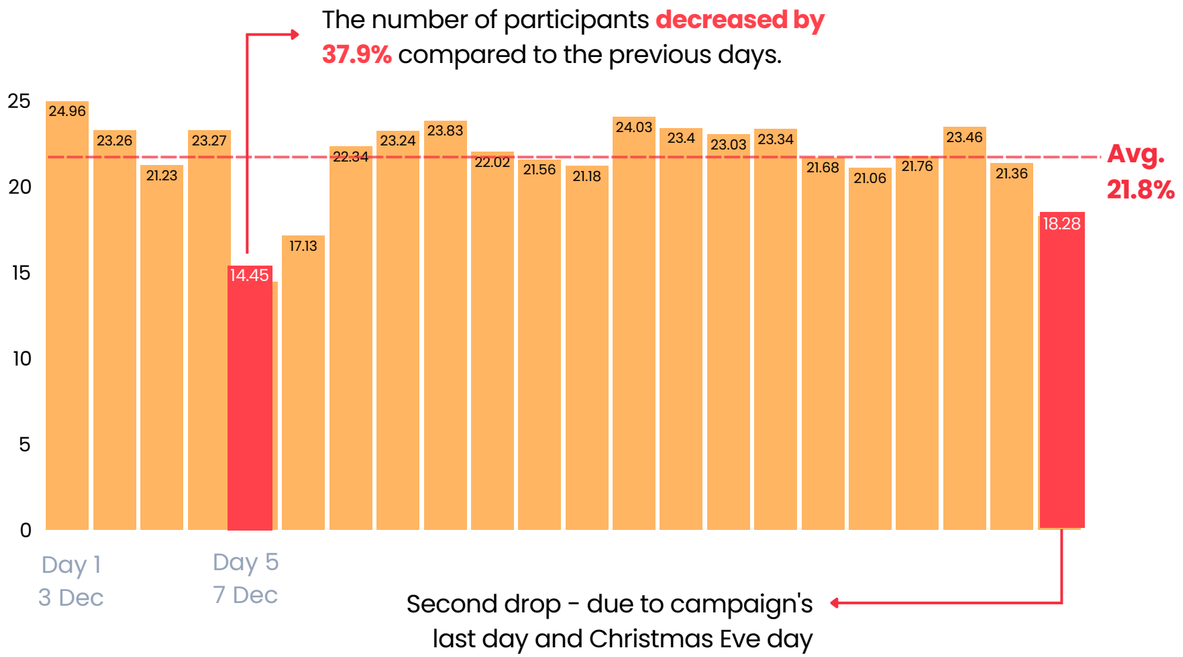
THE "CONSISTENCY GAP": TOTAL CARDS OPENED VS. MAX STREAK'



Day 5 - Biggest Gap: Many users opened total 5 cards but could not keep them for 5 consecutive days.

When being closed to the finish line, users broke their streak at the last stage despite already making it 18+ days streak

DAILY OPEN RATE TREND (%) (83,738 TOTAL CARDS OPENED)



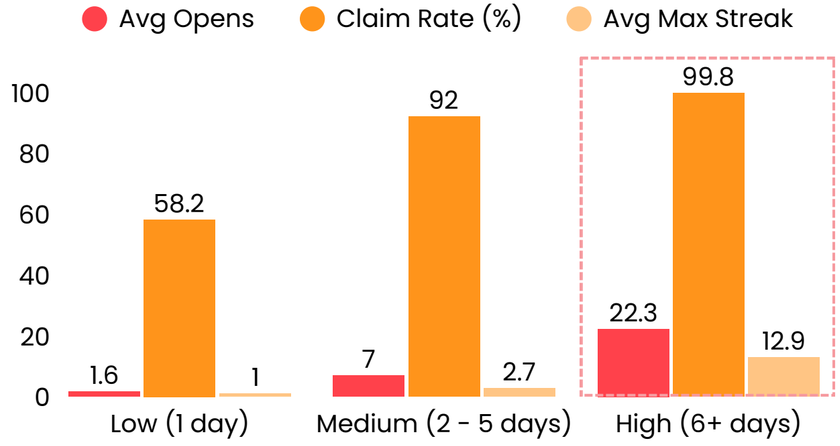
22.4% Avg Weekday Open Rate | **20.3%** Avg Weekend Open Rate (Across 22 days)

Potential cause of Day 5:

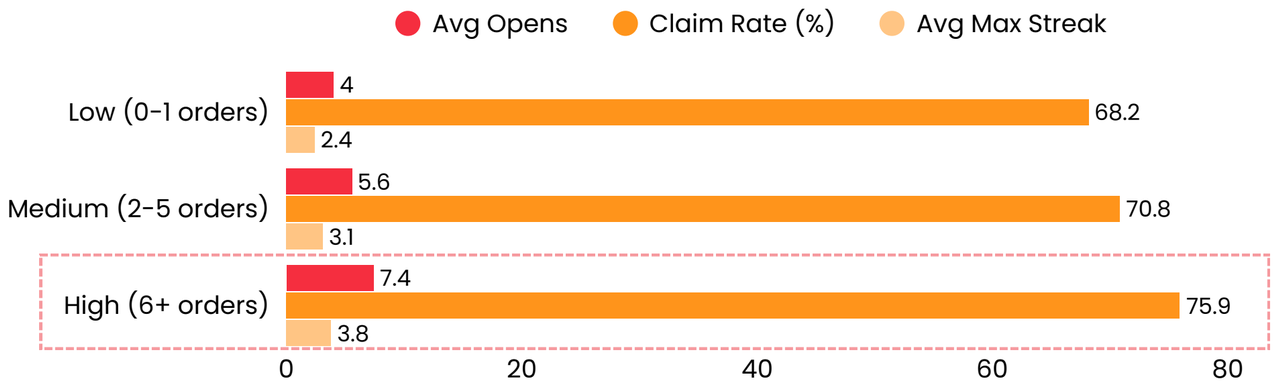
- Weekend effect (weekend was lower by 2.1pp), but it is not the main reason because the average open rate on Saturday is 19.13%
- "Tip" themed titles likely generated weaker motivation compared to more reward driven messages such as "Gift" or "Discount" (Win/Coupon).

Behavioural Loyalty Drives Engagement not Demographics

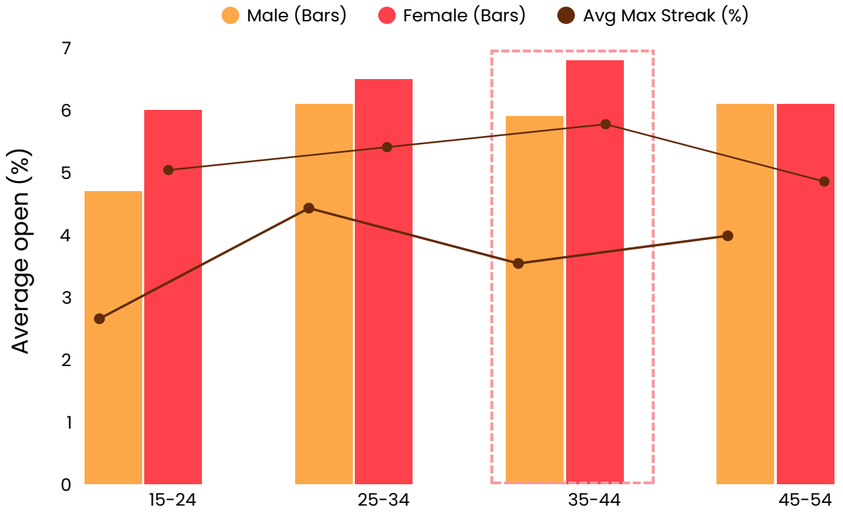
STREAK PARTICIPATION IS THE #1 DRIVER OF OPENS AND CLAIMS



PAST PURCHASE LOYALTY STRONGLY PREDICTS CAMPAIGN BEHAVIOUR



FEMALE OUTPERFORM MALES IN EVERY AGE GROUP



Core Insight: Engagement is driven by behaviour (past orders + streak participation) and Gender × Age — not geography or tenure. Priority targets: 35-44 females + high-loyalty customers for maximum opens, claims and revenue impact.

BUSINESS TAKEAWAY:

1) Strongest signals: Streak behaviour + pre-campaign order history + Gender × Age
2) Females consistently beat males (especially 35-44 group)
3) High-order-history customers show +85% more opens and +11pp higher claim rate
4) High-streak users (6+ days) generate 14× more opens and near-perfect claim rate
5) Weak signals: Urbanization, tenure, province and device show only minor differences
6) Fashion/lifestyle buyers engage deeper than functional shoppers

Segments chosen because they show the largest, most consistent and behaviourally meaningful differences in open rate, claim rate and streak length. Desktop streak anomaly noted (longest streaks (~3.7 days) despite low volume).

Card Selection Behaviour Among Highly Engaged Users

HIGH INTEREST BUT REDEMPTION FRICTION DUE TO SPEND THRESHOLDS

WIN #1

Opens	8,203
Claims	7,252

Claim Rate
88.41%

STREAK #2

Selected	2,053	
Used	1,357	-33.9%

Claim Rate
66.09%

COUPON #3

Opens	13,239	
Claims	8,218	-37.93%

Claim Rate
62.07%

TIP #4

Opens	7,169	
Claims	4,378	-38.93%

Claim Rate
61.07%

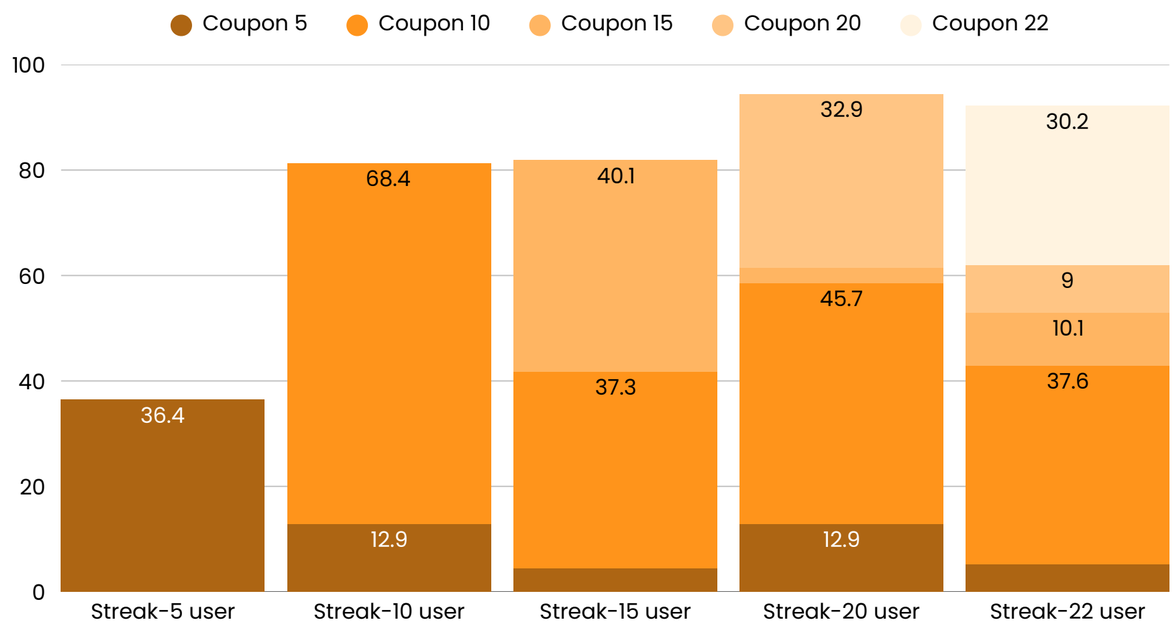
BUSINESS TAKEAWAY:

1) Win cards outperform other cards due to their broad value and no category restrictions.

2) Coupon streak 10 dominates all streak levels, including streak 20 (45.7%) and streak 22 (37.6%). Users with high streaks still choose coupons lower than the tier they unlock — not because they lack spending power (ABV ~€97.9-113 is fairly consistent), but because the perceived value of Coupon 10 is higher than the higher tiers.

3) 84.8% of users selected rewards below their achievable streak tier due to redemption friction from higher minimum spend thresholds.

STREAK CARD SELECTION BY USER (%)



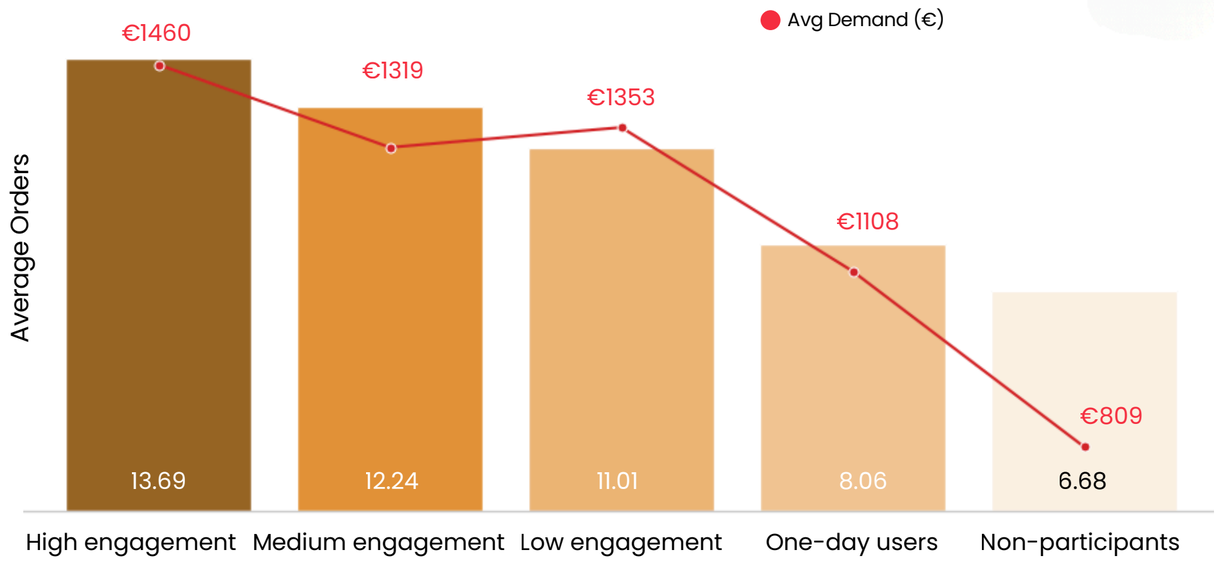
HISTORICAL SPENDING (ABV = AVERAGE BASKET VALUE)

Selected Tier	Number of users	Avg pre-campaign ABV	Avg pre-campaign orders
5	644	97.9	12.9
10	983	98.4	13.2
15	295	113.	18.4
20	74	99.1	13.6
22	57	96.8	21.0

Self-Selection of Loyal Users with Strong but Fragile Habit Rebuilding

PRE-CAMPAIGN AVG ORDERS (NUMBER OF ORDERS) AND AVG DEMAND (€)

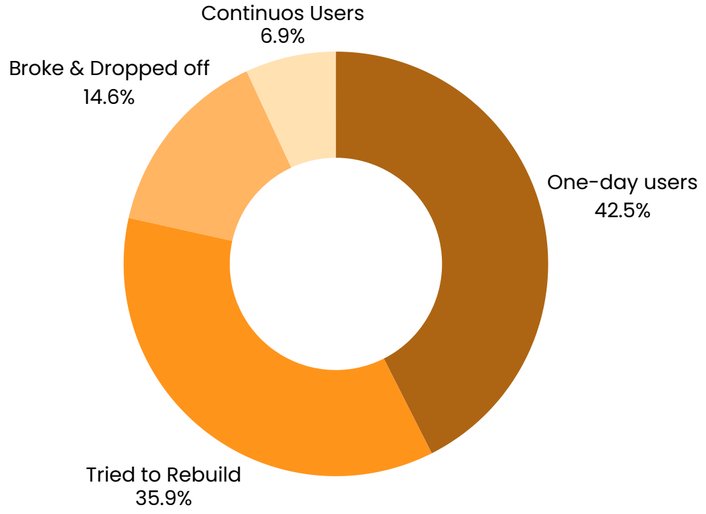
STRONG SELF SELECTION BIAS: High-engagement users were already high-value before the campaign



Psychology takeaway

- Campaign showed strong self-selection: Mostly activated existing loyal, high-value customers
- Streak mechanic created psychological friction: 50.5% of multi-day users (35.9% tried to rebuild + 14.6% dropped) experienced a break
- 35.9% tried to rebuild → users are motivated, but current strict reset hurts retention

STREAK REBUILDING BEHAVIOUR



- **One-Day Users(Open 1 card throughout campaign):** Strong first-day appeal, but failed to convert to Day 2
- **Tried to Rebuild(Participated multiple days, missed at least 1 day) → Biggest opportunity**: Users wanted to continue but lacked support after a miss
- **Broke & Dropped Off(Built small streak once):** Streak break = strong churn trigger
- **Continuous Users(Build long streak):** True loyal core – protect and nurture

BUSINESS TAKEAWAYS:

- Core Insight: The campaign successfully engaged loyal customers but lost many due to rigid streak mechanics.
- Opportunity: Convert the large "Tried to Rebuild" group (35.9%) into consistent users by adding habit-support features → higher retention and long-term demand.

Campaign Delivered Significant Uplift in Orders and Demand

CAMPAIGN GENERATED - 310K IN INCREMENTAL REVENUE

€310,341

Campaign-attributable daily lift	+€0.88
Campaign length	22 days
Incremental demand per participant	€19.36
Total participants	16030

BUSINESS TAKEAWAYS:

1) Pre-, during and post-campaign ORDERS AND DEMAND

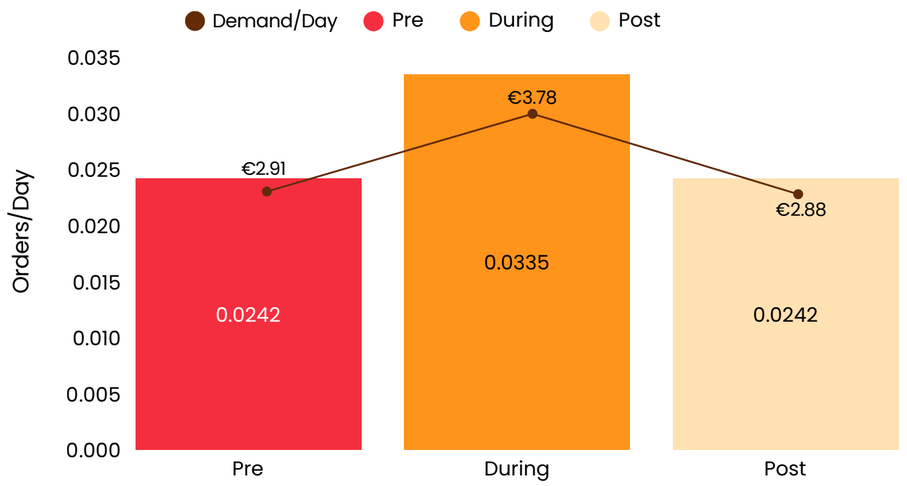
- Both orders and demand spiked sharply during the 22-day campaign.
- They returned almost exactly to baseline after the campaign ended

→ shows a temporary but clear lift during Wannagive days.

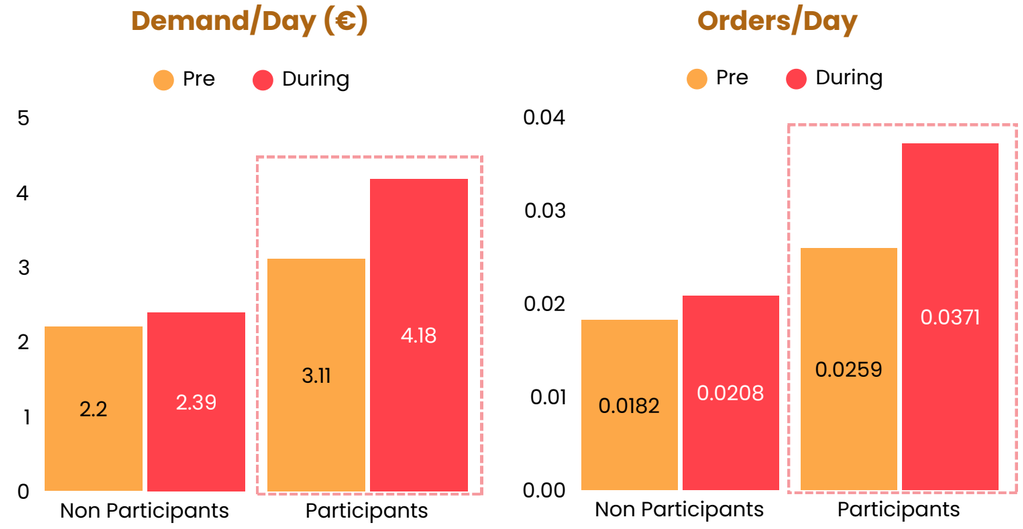
2) Participants out performed non participants

- Participants were already more active before the campaign.
- During the campaign they outperformed non-participants by a wide margin.
- The gap is much larger than seasonality alone would explain.

PRE-, DURING AND POST-CAMPAIGN ORDERS AND DEMAND



PARTICIPANTS OUTPERFORM NON-PARTICIPANTS

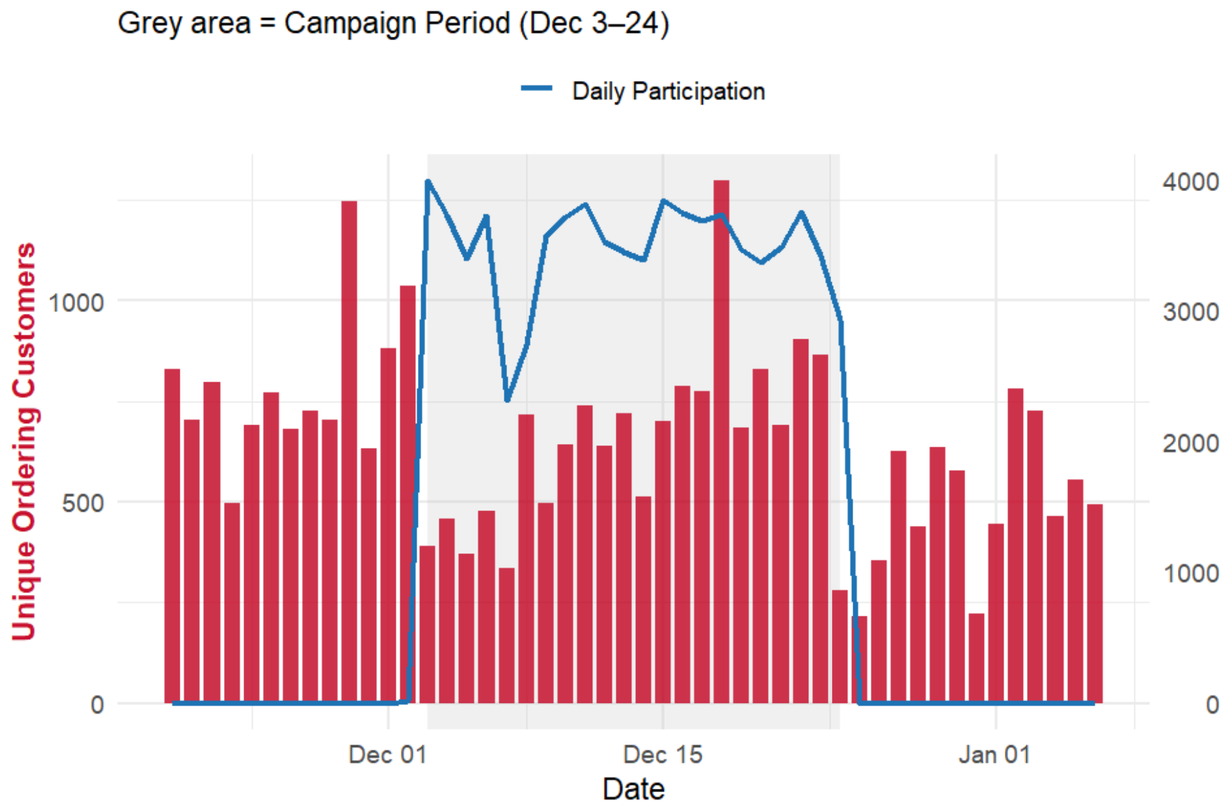


High Engagement Peaks but Limited Conversion into Incremental Orders

DO PARTICIPATION SPIKES TRANSLATE INTO MORE ORDERING CUSTOMERS?

Campaign = strong engagement tool, weak sales driver
Incremental impact on transactions was limited

Seasonal demand & purchase urgency > participation levels & reward mechanics



BUSINESS TAKEAWAYS:

1) Pre-existing Holiday Demand

- High-ordering customers already active before campaign, peaking in late Nov – early Dec
- Ordering behaviour largely reflects seasonal, holiday-driven demand — not campaign mechanics

2) Engagement vs. Conversion

- Daily participation jumped from ~0 to 3,000–4,000 active users during campaign
- Surge in engagement did NOT translate proportionally into more ordering customers → weak conversion effect

3) The December 18 Peak

- Highest order volume coincided with €5 flat discount on Dec 18
- Same €5 discount on Dec 8 generated far fewer orders

→ Timing & pre-Christmas urgency were the real drivers, not the discount itself

Streak Logic Bug & Data Limitations Impacting Campaign Evaluation

Critical Streak Logic Bug: Streaks did not reset after missed days

Metric	Value	Intepretation
Users affected by streak bug (inconsistency)	1,844	11.5% of gapped users had at least one case where streak did not reset properly
Total buggy gap events	3,435	Instances where a user returned after a skip but streak was wrong
% of gap events that were buggy	10.0%	
Average streak inflation when bug occurred	+6.59 levels	On average, buggy streaks were credited ~6.6 extra days too high
Affected users who selected a streak coupon	1,239	67% of the 1,844 buggy users actually selected a New Year's discount coupon
Affected users who used it in a transaction	680	55% of selectors (≈37% of buggy users) actually redeemed it

Data inconsistency
Incorrect mapping of streak card in user info tab

New customer acquisition error
Clear decline in new customer acquisition in recent years

34.8% of ALL campaign discounts came from this bug

Real Customer Journey Example

```text
Dec 13   → Participate   → Logged streak = 7
Dec 14   → Missed day
Dec 15   → Participate   → Logged streak = 6   ← SHOULD BE 1
Dec 16   → Participate   → Logged streak = 7   ← SHOULD BE 2
```

Unique_customer_id = +"8V6LCxOkFZewOqzj0nnfOs8Hjg="

Data Limitation

- No randomized control group – participation is self-selected, limiting causal attribution of campaign impact.
- Missing campaign exposure data (impressions/notifications), preventing distinction between non-exposure and disengagement.
- Lack of cost and margin data – incremental demand can be measured, but true ROI and profitability cannot be fully evaluated.
- Strong seasonal effects (holiday period) confound the isolation of pure campaign impact.

Redesigning Wannagive for Higher Retention, Conversion & Profitability

High engagement but weak habit formation and limited transactional conversion indicate
A need for behavioural, reward and targeting redesign

Redesign Streak Mechanics to Support Habit Formation

Introduce 1–2 “grace days” before streak resets

Add milestone rewards (Day 3, Day 7, Day 14) instead of only final streak focus

Implement streak recovery features (e.g., “streak freeze” tokens)

Longer streaks increase engagement consistency, claims, and long-term customer lifetime value.

Shift from High-Friction Coupons to Flexible, High-Redemption Rewards

Increase proportion of universal rewards (sitewide discounts)

Reduce minimum spend thresholds on coupons

Offer smaller, frequent rewards instead of large end-only rewards

Higher redemption and sustained engagement outperform unused high-value coupons

Position Wannagive as a Loyalty Activation Tool

Personalize campaigns based on loyalty tier

Offer easier entry incentives for low-tenure users

Use CRM segmentation instead of uniform campaign exposure

Maximizes ROI by deepening engagement among high-LTV customers

Convert Engagement into Actual Orders

Add time-limited purchase boosters (e.g., “Order Today for Extra Reward”)

Integrate personalized product nudges during streak progression

Use category-specific incentives instead of flat rewards

Transforms engagement activity into measurable incremental revenue

Variable Description

Slide 2

1. Campaign Opens = Count of unique users who entered the campaign (event = “Enter”)
2. Campaign Onboarded = Count of unique users who onboarded the campaign (event = “onboarding_completed”)
3. Participated = Customers with at least one valid card interaction. (event = “opened”)
4. Max_streak = Maximum number of consecutive active days per user
5. Median Streak Length = Median max_streak of all users
6. Retention Curve = % of users active on Day t since first participation (cohort-based).

Slide 3

1. Total Cards Opened = Total number of card open events per unique_customer_id during campaign period
2. Max Streak = Maximum number of consecutive active days per user
3. Streak Distribution = Count of distinct unique_customer_id grouped by their max_streak, where max_streak is the maximum number of consecutive days a user opened ≥1 campaign card during the campaign period.
4. Daily Open Rate (%) = (Number of unique users who opened a card on a given day ÷ Total active campaign participants) × 100

Slide 4

1. Unit of analysis = customer-level aggregation.
2. n_opens = Total number of campaign engagement actions per user, defined as the sum of “participate” events and “collectable_interaction” events with action = “opened” during the campaign period.
3. Avg Opens = Mean number of card open events per customer (n_opens) during campaign period.
4. n_claims = Total number of reward claim events per user, identified from collectable_interaction events where action = “claimed” during the campaign period.
5. Claim Rate (%) = % of customers with ≥1 claim (n_claims > 0) within each segment.
6. Avg Max Streak = Mean of maximum consecutive active days (system-logged max_streak) per customer.
7. Loyalty segments are based on pre-campaign order frequency.

Slide 5

1. Opens (by Card Type) = Count of unique customers associated with each collectableType(win, coupon & tip), representing user-level card interaction rather than total open events.
2. Claims (Regular Cards) = Distinct customers who claimed a reward associated with a specific collectableType based on collectable_interaction events with action = “claimed”.
3. Claim Rate (%) = Number of “claimed” events ÷ number of “opened” events for each card type (collectable_interaction logs).
4. Streak Selection = Distinct users with a recorded streak reward selection (action = “selected”).
5. Streak Redemption Rate (%) = Users who redeemed a selected streak reward ÷ users who selected a streak reward.
6. Pre-Campaign ABV = Total demand ÷ number of orders per user using transaction data before Dec 3, 2024.
7. Pre-Campaign Orders = Average number of transactions per user before the campaign, grouped by max_streak segments.

Slide 6

1. Engagement Segment = Customer grouping based on maximum campaign streak (max_streak) and participation status, where segments include Non-participants, One-day users, Low (2–5 days), Medium (6–14 days), and High engagement (≥15 days).
2. Average Pre-Campaign Orders = Mean number of transactions per customer before the campaign start date (Dec 3, 2024), derived from the transaction table and aggregated at the unique_customer_id level.
3. Average Pre-Campaign Demand (€) = Mean total monetary demand per customer before the campaign period, calculated from transaction demand values and aggregated by engagement segment.
4. Self-Selection = Comparison of pre-campaign behavioural metrics (orders and demand) across engagement segments to assess whether highly engaged users were already higher-value customers.
5. Daily Participation = Distinct daily participation events per user, defined using “participate” event logs aggregated at the date level during the campaign period.
6. Streak Break = A gap of more than one day between consecutive participation dates (gap_days > 1), indicating a disruption in consecutive engagement.

Variable Description

Slide 6 (Continued)

1. Rebuild Segment = Count of unique_customers in each segment defined below
   a. One-Day Users (No Streak) = Participants who recorded activity on only one distinct campaign day (based on "participate" events) and did not return on any subsequent day.
   b. Continuous Users (No Breaks) = Participants with activity on multiple campaign days and no gaps greater than one day between consecutive participation dates (i.e., fully consistent engagement without streak interruptions).
   c. Tried to Rebuild Streak = Users who experienced at least one participation gap (streak break) and returned to participate again after the break within the campaign period.
   d. Broke & Dropped Off = Participants who experienced a break in consecutive participation (gap > 1 day) and did not return to participate after the first streak break during the campaign period.

Slide 7

1. Master Dataset = User-level analytical table aggregating transaction behaviour (orders and demand) across pre-campaign, during-campaign, and post-campaign periods for each unique_customer_id.
2. Orders per Day (Period) = Total orders in a given period divided by the number of days in that period, averaged across customers.
3. Participants = Customers with ≥1 "participate" event during the campaign (from Wannagive logs).
4. Non-participants = Customers in the master dataset with no recorded campaign participation.
5. Order Lift = Change in number of orders per customer from pre-campaign to campaign period.
6. Demand Lift (€) = Change in total demand per customer from pre-campaign to campaign period
7. Incremental Daily Demand (Participant-Adjusted) = (Participant demand/day during - Participant demand/day pre) - (Non-participant demand/day during - Non-participant demand/day pre)
8. Incremental Demand per Participant = Adjusted daily demand uplift × 22 campaign days
9. Total Incremental Demand (€) = Incremental demand per participant × total number of participants (16,030)

Slide 8

1. Unique Ordering Customers = Number of distinct customers who placed at least one transaction on a given day, calculated from the transaction table.
2. Daily Participation (Active Users) = Number of distinct users who recorded a "participate" event on a given day in the Wannagive campaign logs.
3. Grey area indicates campaign period (Dec 3–24, 2024).
4. Daily dataset merges transaction records, campaign activity logs, and scheduled reward calendar at the date level.
5. Participation values are rescaled for dual-axis visualization and do not imply direct equivalence with ordering volume.

Slide 9

1. Activity Date = Calendar date of a user's participation event, derived from the event timestamp and used to reconstruct daily engagement sequences.
2. Current Streak Value = System-recorded streak level logged in the Wannagive event data for each participation day.
3. Missed Day = Indicator variable identifying gaps in consecutive participation (gap > 1 day), implying a break in behavioural streak continuity.
4. Inconsistent Streak = Cases where a user skipped one or more days (missed_day = TRUE) but the system-reported streak value remained greater than 1, indicating that the streak did not reset despite a participation gap.
5. Affected Customers = Users who experienced at least one instance of inconsistent streak logging during the campaign period.
6. Streak Reward Selection = Distinct users who selected a streak-based reward (NIEUWJAARSKORTING codes) from the campaign reward interface
7. Reward Usage = Transactions where selected streak reward codes were actually redeemed and resulted in a positive coupon discount.
8. Actual Revenue Leakage (€) = Total monetary value of coupon discounts redeemed by users affected by inconsistent streak logic.
